Abstract

Agriculture remains the foundation of India's socioeconomic fabric, engaging approximately 54.6 per cent of the total workforce and contributing 18.4 per cent to Gross Value Added. The rapid proliferation of digital technologies encompassing the Internet of Things (IoT), artificial intelligence (AI), remote sensing, precision agriculture platforms, and digital public infrastructure has inaugurated a transformative moment for Indian agriculture. Simultaneously, the Himalayan Agro-Ecological zone, spanning Jammu & Kashmir, Himachal Pradesh, Uttarakhand, and the North-Eastern hill states, presents both a compelling frontier for digital intervention and a deeply challenging terrain for adoption. This chapter undertakes a systematic, research-augmented inquiry into the opportunities, structural challenges, and forward-looking pathways of digital agriculture in India, with particularised focus on the Himalayan region. Drawing upon a comprehensive review of peer-reviewed literature, policy documents, empirical studies, and field-level evidence, the analysis reveals that while digital agriculture holds unprecedented potential to enhance productivity, climate resilience, and market access, its diffusion across Himalayan smallholders is critically constrained by infrastructural deficits, digital illiteracy, terrain-driven inaccessibility, and the feminisation of mountain agriculture consequent upon sustained male out-migration. The chapter argues for a differentiated, context-sensitive approach to digital agriculture policy that prioritises mountain-specific solutions, inclusive governance frameworks, and capacity-building as necessary preconditions for technological uptake. The study concludes with actionable policy insights and a research agenda for the next phase of digital agricultural transformation in India.

Keywords: Digital agriculture, precision farming, Himalayan agriculture, IoT, remote sensing.

1. Introduction

The twenty-first century has ushered in an era often characterised as Agriculture 4.0, a paradigm that integrates digital technologies, data-driven intelligence, and network-based farm supervision into the core of agricultural production systems (Parra-Lopez *et al.*, 2024). Defined as the consistent application of precision agriculture methods, internal and external networking of the farm, and the use of web-based data platforms together with big data analyses, digital agriculture is reshaping how food is grown, managed, and distributed (Balkrishna *et al.*, 2023). The technologies central to this transformation, including the Internet of Things (IoT), artificial intelligence (AI), remote sensing, geographic information systems (GIS), unmanned aerial

vehicles (UAVs or drones), cloud computing, and blockchain have moved from the realm of experimental research to practical on-farm deployment across several regions of the world.

India occupies a particularly consequential position in this global agricultural transition. With over 93 million agricultural households and a food production record of 357.73 million tonnes of foodgrains and 369.05 million tonnes of horticulture produce in 2024–25, India's agricultural sector is at a scale where even marginal improvements in efficiency, resource use, and market access can yield transformational national outcomes (Agricultural Statistics, 2024-25; Kumar *et al.*, 2025). Yet, the structural composition of Indian agriculture, characterised by 89.4 per cent of agricultural households owning less than two hectares of land, seasonal rainfall dependency, persistent soil health degradation, and fragmented market linkages demands solutions that are not merely technologically sophisticated but contextually appropriate, affordable, and scalable (Agricultural Statistics, 2024-25; Kumar *et al.*, 2025).

Within this national tableau, the Himalayan agricultural zone constitutes an especially critical sub-field of inquiry. The Indian Himalayan Region (IHR) encompassing the states of Jammu and Kashmir, Ladakh, Himachal Pradesh, Uttarakhand, Sikkim, and the hill districts of the North-Eastern states supports millions of smallholder farming households practising largely subsistence and rain-fed agriculture across diverse agro-climatic zones ranging from tropical foothills to cold alpine pastures. Agriculture here is not merely an economic activity; it is embedded in centuries of indigenous ecological knowledge, cultural identity, and community food systems. However, Himalayan agriculture is under compounding stress. Climate change has manifested as rising mean annual temperatures, erratic precipitation patterns, glacial retreat, and increased frequency of extreme weather events, all of which are degrading the agro-ecological foundations of mountain farming (Sati & Kumar, 2023). Simultaneously, chronic out-migration of educated rural youth, driven by constrained economic opportunities, harsh terrain, and limited agricultural returns, has led to sustained depopulation of mountain villages, feminisation of agricultural labour, and the abandonment of terraced farmland (Upadhyay, 2024; Naudiyal *et al.*, 2019; RDMC, 2018). The outmigration is contributing to the abandonment of villages & habitats. Moreover, due to climate change and declining cultivation crop races or cultivars are disappearing (Sati & Kumar, 2023). These converging crises, ecological, demographic, and economic, render Himalayan agriculture a zone of urgent policy and research attention.

Despite a growing body of scholarship on digital agriculture in India, the academic literature overwhelmingly addresses the agrarian plains i.e. Punjab, Maharashtra, Andhra Pradesh, and similar high-productivity zones where infrastructure is relatively developed and land holdings are more amenable to technological intervention (Kumar *et al.*, 2025; Balkrishna *et al.*, 2023). The Himalayan region, by contrast, has received disproportionately limited attention in digital agriculture discourse, even as it faces the most acute convergence of challenges that digital solutions are designed to address, climate variability, market isolation, labour scarcity, and knowledge deficits. Also, there is a near-absence of synthesis literature that maps the specific technological opportunities available for mountain smallholders within India's digital agriculture policy architecture. Moreover, the barriers to digital technology adoption in high-altitude, terrain-fragmented, and connectivity-deficient environments remain under-theorised. Besides, the intersection between Himalayan out-migration, feminisation of agriculture, and digital literacy constraints has not been adequately examined in the context of technology uptake.

Within this contextual background, the current study is motivated by the conviction that a generic, undifferentiated approach to digital agriculture will systematically exclude mountain farmers, the

very population most in need of transformative intervention. Furthermore, India's Digital Agriculture Mission, launched in September 2024 with a financial outlay of Rs. 2,817 crore and a mandate to create digital public infrastructure for agriculture, represents a historic policy window that, if not purposively designed for mountain contexts, risks deepening agrarian inequities between the plains and the mountains (Government of India, 2024). Therefore, the study examines the landscape of digital agriculture and national policy architecture for digital agriculture in India. Also, it focuses on specific opportunities that digital agriculture presents for Himalayan farming systems along with the systematic identification of the structural, infrastructural, socio-cultural, and institutional challenges that impede digital agriculture adoption in mountain regions.

2. Conceptualising Digital Agriculture

Digital agriculture, often used interchangeably with precision agriculture, smart farming, and Agriculture 4.0, refers to the application of modern information and communication technologies (ICTs) to improve farm management decision-making, enhance resource use efficiency, and strengthen the sustainability of agricultural systems (Parra-Lopez *et al.*, 2024; Balkrishna *et al.*, 2023). The conceptual underpinning of digital agriculture draws from multiple intellectual traditions. From the field of development economics, it resonates with Amartya Sen's Capability Approach, which positions technology as an enabler of human freedoms and agricultural choice (Frediani, 2010; Lambe *et al.*, 2022). From agronomy and systems ecology, it reflects the precision farming paradigm, originally developed in the 1990s, which sought to replace uniform input application across fields with site-specific, variability-responsive management (Lanucara *et al.*, 2024; Khan & Munawar, 2023). From the sociology of technology, it engages with questions of technology adoption, diffusion, and digital divide, particularly the Rural-Urban Tele-density gap, currently Urban: 133.72% vs. Rural: 59.19% as of March 2024, that structures unequal access to digital tools (Telecom Regulatory Authority of India, 2024).

Balasundram *et al.* (2023) and Parra-Lopez *et al.* (2024) distinguish four interconnected dimensions of digital agriculture: (a) digital production technologies (IoT sensors, UAVs, GPS-guided machinery); (b) digital decision support systems (AI-based crop models, weather analytics); (c) digital market and financial access platforms (eNAM, AgriStack, mobile payment systems); and (d) digital governance infrastructure (digital farmer registries, remote crop surveys, satellite-based insurance systems). These dimensions are complementary but not uniformly deployable across all agricultural environments, a distinction that is especially salient for the Himalayan context. The integration of IoT and AI in agriculture has resulted in a dramatic increase in research, reflecting intensified academic and industrial interest in smart farming solutions globally (Miller *et al.*, 2025). From a geographical perspective, India, China, and Saudi Arabia have emerged as the top contributors to research output in this domain, driven by large-scale government investments and national digital agriculture strategies (Miller *et al.*, 2025). IoT-based sensor networks form the technological backbone of precision agriculture. Soil moisture sensors connected via low-power wide-area networks (LPWAN) provide real-time insights into root zone hydration, while temperature and humidity sensors enable automated greenhouse management and climate-responsive cultivation decisions (Bwambale *et al.*, 2022; Abioye *et al.*, 2022; Sui, 2017; Kanimozhi & Vadivel, 2024).

Unmanned aerial vehicles (UAVs) equipped with multispectral cameras and sensors have enabled high-resolution field surveillance, early pest and disease detection, and precision application of agrochemicals (Lanucara *et al.*, 2024; Khan & Munawar, 2023; Miller *et al.*, 2025). The integration of machine learning algorithms, particularly Support Vector Machines (SVMs),

Convolutional Neural Networks (CNNs), and random forests, with sensor data has created predictive capabilities for crop yield estimation, disease outbreak forecasting, and irrigation scheduling (Miller et al., 2025; Mansoor et al., 2025). Cloud computing platforms enable the aggregation and analysis of heterogeneous agricultural data at scale, while edge computing reduces latency for real-time decision support at the farm level (Narwane *et al.*, 2022; Nemenyi *et al.*, 2003). Remote sensing using satellite imagery has progressed significantly with the availability of Sentinel-2 and Landsat datasets, enabling soil moisture mapping, crop health monitoring, yield forecasting, and agricultural drought assessment at regional and national scales (Jędrejek & Pudelko, 2023; Segarra *et al.*, 2020). In India, the Krishi Decision Support System (Krishi DSS), launched in August 2024, represents a landmark attempt to integrate remote sensing data on crops, soil, weather, and water resources into a comprehensive geospatial decision platform (Government of India, 2024).

India's digital agriculture ecosystem has evolved along three broad phases. The first phase (2000–2015) was characterised by ICT-for-information initiatives like Kisan Call Centres, the National e-Governance Plan in Agriculture (NeGP-A), and state-level agricultural portals, that aimed primarily at improving information access for farmers (Balkrishna *et al.*, 2023). The second phase (2015–2022), coinciding with Digital India, saw the emergence of mobile-based agricultural advisory platforms, e-NAM for market linkages, PM-KISAN for digital direct benefit transfers, and early precision agriculture pilot projects (Balkrishna *et al.*, 2023; Kumar *et al.*, 2025). The third and current phase (2022–present) is defined by the ambition of Digital Public Infrastructure (DPI) for agriculture, a comprehensive, interoperable, and farmer-centric data architecture that integrates farmer registries (AgriStack), crop sown registries, soil profile maps, and satellite-based crop estimation systems (Government of India, 2024).

DPI for agriculture, and its operationalisation accelerated through the Digital Agriculture Mission, with a central government share of Rs. 1,940 crores within a total outlay of Rs. 2,817 crore (Government of India, 2024). This Mission aims to create digital farmer IDs for 11 crore farmers over three years, conduct a nationwide Digital Crop Survey, and develop soil profile maps at a 1:10,000 scale for 142 million hectares of agricultural land, of which 29 million hectares are already mapped (Government of India, 2024). The Krishi DSS will be the analytical backbone of this infrastructure, providing geospatial integration of crop, soil, weather, and water resource data. Research evidence confirms that India's precision agriculture market, estimated at approximately USD 102 million in 2023, is projected to grow at a compound annual growth rate (CAGR) exceeding 10 per cent, potentially reaching USD 220 million by 2031 (BioBiz Consulting, 2024). Indian agri-tech startups such as Fasal (IoT-based precision irrigation), TartanSense (AI-powered weed detection robots), and Farmonaut (satellite-based farm monitoring) represent a vibrant private sector ecosystem that is complementing public investments in digital agriculture infrastructure.

3. Himalayan Agriculture: Historical Trajectory & Contemporary Challenges

Himalayan agriculture is structurally distinct from the plains in several critical dimensions. The Indian Himalayan Region is characterised by diverse agro-climatic zones, from tropical foothills (<500m) to sub-tropical (500–1000m), temperate (1000–2000m), and alpine zones (>2000m) each with unique crop systems, water regimes, and ecological constraints (Sati & Kumar, 2023). Historically, terraced agriculture supported high agro biodiversity, with complex systems of crop rotation, mixed farming, and indigenous water harvesting that sustained mountain communities over centuries. The temperate zone alone hosts principal crops including paddy, wheat, barley, five

races of millets, four races of oilseeds, twelve races of pulses, citrus fruits, apples, pears, peaches, plums, apricots, and walnuts (Sati & Kumar, 2023).

The contemporary crisis of Himalayan agriculture is multi-causal and mutually reinforcing. Climate change has caused measurable disruption in rising mean annual temperatures, reduction in rainfall & number of rainy days, increased frequency of flash floods, landslides, and cloud bursts, and glacial retreat that threatens irrigation water availability (Tiwari & Joshi, 2015; Upadhyay, 2024). Climate change projections suggest that approximately 50 per cent of the Himalayan population is at risk of malnutrition and food insecurity (Rasul *et al.*, 2019, Sati & Kumar, 2023). Moreover, research also confirms that South Asian Mountain regions face disproportionate risks from climate change, including cascading impacts on water security, agricultural productivity, and livelihoods (IPCC, 2022).

Out-migration constitutes the second major structural driver of agricultural decline in the Himalayas. Sustained outmigration has led to farm exit and abandonment of land in the Indian Himalayan Region (Upadhyay, 2024; Naudiyal *et al.*, 2019). Continued outmigration has led to the abandonment of villages and steadily declining of agricultural sector (Tiwari & Joshi, 2015). Moreover, the increasing trend of outmigration among male youth has caused a significant feminisation of mountain agriculture, increased women's workload while reducing household labour availability for intensive farming operations. Remittances from migration, while providing short-term household income, are primarily used for meeting everyday consumption needs and are not systematically reinvested in climate change adaptation or agricultural infrastructure (Upadhyay, 2024). Also, the conversion of agricultural land into horticulture in Himalayan states reveals another dimension i.e. the rapid commercialisation of agriculture, driven by export-oriented monoculture crop such as apple, has brought transformative but mixed consequences. Yet this commercialisation, while increasing farm revenues in aggregate, has also produced agrarian extractivism, increased input dependency, decrease in rice cultivation and erosion of crop diversity among smallholders (Mushtaq & Goswami, 2024).

The global literature on digital agriculture for smallholder farmers reveals a consistent pattern of promise tempered by structural barriers. Systematic reviews by Gumbi *et al.* (2023) and Choruma *et al.* (2024) identify digital infrastructure deficits, affordability constraints, low digital literacy, and gender disparities as the primary obstacles to digital agriculture adoption among smallholders in the Global South. Cui & Wang (2023) and Hoang & Tran (2023) document that the decision to adopt digital agricultural technologies is significantly shaped by farmers' education levels, age, farm size, distance to markets, and access to extension services. Particularly relevant for the Himalayan context is the finding by Gumbi *et al.* (2023) that most challenges in digital agriculture adoption concern digital infrastructure, affordability, and digital literacy or skills. These authors note that digital agriculture is still a nascent concept to smallholder farmers, with a lack of understanding of its value being a fundamental adoption barrier. The systematic review by Yuan & Sun (2024), analysing the digital transformation of smallholder agriculture through a government–technology–smallholder analytical framework, identifies inadequate digital agriculture policies, limited availability of contextually appropriate digital applications, insufficient resources among smallholder farmers, and constraints imposed by social and cultural factors as key challenges requiring integrated multi-stakeholder responses.

Evidence from the Himalayan sub-region is emerging but remains thin. Research on digital ecosystem potential documents that technology adoption differs significantly between large and

small farmers, with the latter facing constraints around market information, post-harvest management, and value chain integration (Sharma *et al.*, 2024).

4 Methodological Approach and Philosophical Stance

This chapter adopts an interpretive, systematic review methodology augmented by secondary data analysis. The study does not generate primary empirical data; rather, it undertakes a rigorous synthesis of existing peer-reviewed research, official policy documents, government statistical publications, and credible institutional reports to construct a theoretically grounded, empirically substantiated analysis of digital agriculture in India with special reference to the Himalayan region. The philosophical underpinning is pragmatist, treating knowledge as contextually situated and methodology as instrumentally chosen to address the research problem. This stance is appropriate for a chapter that seeks to span multiple scales (national and regional), multiple disciplinary traditions (agronomy, development economics, geography, computer science, and rural sociology), and multiple types of evidence (quantitative statistics, qualitative case narratives, policy analysis, and technology assessment). The literature search was conducted across multiple academic databases including Web of Science, Scopus, ScienceDirect, PubMed/PMC, Google Scholar, and MDPI open-access journals. Search keywords were selected to capture the breadth of the topic: (i) 'digital agriculture India', 'precision agriculture India', 'smart farming India'; (ii) 'IoT agriculture', 'remote sensing agriculture', 'AI farming India'; (iii) 'Himalayan agriculture', 'mountain farming India', 'Uttarakhand agriculture', 'Jammu Kashmir agriculture', 'Himachal Pradesh agriculture'; (iv) 'smallholder digital agriculture', 'technology adoption smallholder India'; (v) 'out-migration Himalaya', 'climate change Himalayan agriculture', 'land abandonment Uttarakhand'. Boolean operators (AND, OR) were systematically applied to generate targeted search strings.

Inclusion criteria required that studies: (a) be published in peer-reviewed journals, edited academic volumes, or authoritative institutional reports; (b) be published between 2015 and 2025 to ensure contemporary relevance, with exceptions made for seminal foundational works; (c) be directly relevant to digital agriculture technologies, smallholder adoption dynamics, or Himalayan/mountain agricultural systems; and (d) provide empirical evidence, systematic review findings, or rigorous policy analysis. Grey literature from the Government of India (Ministry of Agriculture and Farmers Welfare, Press Information Bureau, Directorate of Economics and Statistics), ICAR, ICIMOD, FAO, and the World Bank was included given the policy focus of the chapter. After applying exclusion criteria (non-peer-reviewed opinion pieces, anecdotal reports, geographically irrelevant studies), the final review corpus comprised over 60 academic sources and 15 official policy documents. The chapter deploys a three-layer analytical framework: (i) a technology assessment layer that maps the landscape of digital agricultural technologies and their demonstrated applications; (ii) an adoption and diffusion layer drawing on the Technology Acceptance Model (TAM), the Diffusion of Innovations theory (Rogers, 2003), and the government–technology–smallholder framework of Yuan & Sun (2024); and (iii) a contextual vulnerability layer that analyses the structural conditions, climate exposure, migration dynamics, infrastructure deficits, gender relations, that modulate technology uptake in Himalayan settings.

Findings from the national-level analysis are systematically disaggregated to the Himalayan sub-regional level through purposive mapping of Himalayan-specific evidence. Where direct Himalayan evidence is absent or limited, inferential analysis from comparable mountain and smallholder contexts, has been used with appropriate caveats. The chapter also employs a

comparative analysis of the plains and mountains to illuminate differential digital agriculture opportunities and barriers.

5. Results and Discussion

5.1. Digital Agriculture Opportunities in India: A National Scan

5.1.1. Precision Agriculture and IoT Applications

India's precision agriculture market, while nascent, is demonstrating compelling growth trajectories and demonstrated farm-level benefits. The market is currently estimated at approximately USD 102 million (2023) and is projected to grow at a CAGR exceeding 10 per cent, potentially reaching USD 220 million by 2031 (BioBiz Consulting, 2024). Key states leading in adoption include Punjab, Maharashtra, and Andhra Pradesh, which possess relatively more developed digital infrastructure, larger average farm sizes, and established agri-tech ecosystems (BioBiz Consulting, 2024). The benefits documented in the literature are substantial, precision irrigation driven by IoT sensors has enabled water use reductions, while site-specific nutrient management has reduced fertiliser overuse and its associated costs (Kumar et al., 2025; Vullaganti et al., 2025).

The full technology stack of digital agriculture includes GPS and GIS-based field mapping for management zone delineation; soil sensors monitoring moisture, pH, temperature, and nutrient content; UAVs for crop health surveillance and precision agrochemical application; crop growth simulation models (e.g., DSSAT-CSM) for yield forecasting; machine learning platforms for pest and disease identification; and digital advisory services for crop, weather, and market information (Balkrishna et al., 2023; Miller et al., 2025). Each of these technologies addresses a specific constraint in India's agricultural system, from water scarcity and soil degradation to pest management and market information asymmetry.

5.1.2. The Digital Agriculture Mission: Policy Opportunity

The Digital Agriculture Mission, launched in September 2024 with a financial outlay of Rs. 2,817 crores (including Rs. 1,940 crores from the central government), represents the most comprehensive and architecturally integrated attempt to build a national digital agriculture ecosystem (Government of India, 2024). The mission represents a significant policy initiative aimed at transforming India's agricultural sector through the development of digital public infrastructure, data-driven governance, and technology-enabled farm management systems. By integrating emerging technologies such as artificial intelligence, geospatial analytics, remote sensing, and digital platforms, the mission seeks to enhance productivity, improve decision-making, and strengthen the delivery of agricultural services to farmers (Table 1). The main components of the mission are (a) AgriStack (Kisan ki Pehchaan), a farmer-centric digital public infrastructure that issues unique Farmer IDs linked to land records, demographic data, and crop sown registries, targeting digital identities for 11 crore farmers (b) the Digital Crop Survey (c) the Krishi Decision Support System (DSS), integrating remote sensing data on crops, soil, weather, and water resources into a comprehensive geospatial platform; (d) the Digital General Crop Estimation Survey (DGCES) for precise yield estimates; (e) Soil Profile Mapping at a 1:10,000 scale for 142 million hectares; and (f) enabling Krishi Sakhis as trained para-extension workers, with 2,50,000 positions envisaged (Government of India, 2024).

The Saagu Baagu programme in Telangana, scaled by the state government in October 2023 to cover 500,000 farmers across five crops and ten districts after successful AI-piloting, exemplifies

the transformative potential of digital advisory services for smallholder income augmentation (World Economic Forum, 2024). This initiative demonstrates that AI-based bot advisors and digital marketplaces can meaningfully support smallholding farmers when co-designed with farming communities and embedded in appropriate institutional frameworks.

Table 1: Key Components of India's Digital Agriculture Mission

Mission Component	Description / Functional Scope	Key Targets	Current Performance / Status
AgriStack (Farmer Digital Infrastructure)	Creation of a unified digital database of farmers integrating land records, demographic data, crop information, and scheme benefits through a unique Farmer ID.	Generation of ~11 crore Farmer IDs by 2026–27.	Over 7+ crore Farmer IDs generated across several states; gradual integration with agricultural schemes and services.
Farmer Registry & Crop Sown Registry	Digital registry linking farmers with land parcels and crop details, enabling targeted subsidies, crop insurance, and digital advisory services.	Nationwide digitization of farmer and crop records.	Operational in many states with ongoing data integration through digital crop surveys.
Geo-Referenced Village and Farm Mapping	Development of geo-referenced maps linking village boundaries, farmland parcels, and cropping patterns to support spatial planning and agricultural monitoring.	Digitization of village land maps and geospatial farm databases across India.	Mapping and geospatial integration underway under AgriStack and state land record systems.
Krishi Decision Support System (KDSS)	Geospatial analytics platform integrating satellite data, weather information, soil data, and crop intelligence for real-time advisories and planning.	Development of a national geospatial agricultural intelligence platform.	Pilot systems generating crop monitoring dashboards, yield forecasts, and climate advisories.
Digital Crop Survey (Plot-Level Data Collection)	Mobile-based field surveys capturing real-time crop data and acreage at plot level using geo-tagging and remote sensing integration.	Coverage of all agricultural districts	Implemented in hundreds of districts, covering crores of farm plots during seasonal surveys.
Soil Profile and Digital Soil Mapping	Creation of detailed digital soil health and nutrient maps to enable precision nutrient management and sustainable soil practices.	Soil profiling of ~142 million hectares of agricultural land.	Soil health datasets being integrated with digital advisory platforms.
Digital General Crop Estimation Survey (DGCES)	Technology-enabled crop production estimation using remote sensing, digital surveys, and crop-cutting experiments.	Improve accuracy and timeliness of national crop production estimates.	Pilots underway to integrate satellite imagery with traditional crop estimation methods.
Digital Agriculture Ecosystem (AI, IoT, Blockchain)	Integration of emerging technologies such as artificial intelligence, IoT sensors, drones, and blockchain to enhance farm productivity, traceability, and supply chains.	Development of a Digital Public Infrastructure (DPI) for agriculture.	Mission supported with ₹2,800+ crore investment for digital infrastructure development.
Krishi Sakhis (Digital Community Resource Persons)	Women community extension workers trained to provide farm advisory, promote digital agriculture tools, assist with data collection, and	Training of Krishi Sakhis nationwide to strengthen grassroots	Krishi Sakhis are being trained actively to foster farmers extension services

facilitate adoption of sustainable practices.	agricultural extension.

5.2 Opportunities for Himalayan Agriculture Through Digital Interventions

5.2.1. Climate Resilience and Early Warning Systems

For Himalayan farming communities confronting intensifying climate variability, digital technologies offer the most direct pathway to enhanced adaptive capacity. Remote sensing platforms can provide real-time monitoring of glacial retreat, snowpack depth, and soil moisture levels across terrain inaccessible to field-based monitoring, information critical for irrigation planning, crop scheduling, and disaster preparedness (Parra-Lopez et al., 2024). Satellite-based weather forecasting, integrated with AI analytics and disseminated via mobile applications, can provide hyper-local weather prediction that helps mountain farmers navigate the growing unpredictability of monsoon onset, distribution, and duration. The Climate Corp model, which utilises localised weather data to predict crop yields on historical dataset (Parra-Lopez et al., 2024), provides a template for developing mountain-specific climate intelligence services in India.

Early warning systems for landslides, flash floods, and cloud bursts, all increasingly frequent in the Himalayan region, represent another high-value application of digital technologies for mountain agriculture. When integrated with agricultural advisory systems, such warnings can help farmers take timely protective measures for standing crops and livestock, reducing the considerable economic losses that extreme events impose on Himalayan smallholders. The Himalayan ecosystem services literature confirms that farmers in the Hindu-Kush Himalayan region have already begun adapting through water conservation methods, changing sowing times, and diversifying into perennial crops that are more resilient to water stress (KC *et al.*, 2022).

5.2.2. Market Access and Value Chain Integration

Perhaps the most transformative opportunity for Himalayan agriculture lies in digital market integration. The geographic isolation of mountain farming communities has historically produced severe market information asymmetry, with intermediaries capturing disproportionate margins across apple, vegetable, spice, and handicraft value chains. Digital platforms connecting farmers directly to consumers on the model of eNAM for grains or HFN Agritech's cooperative model in Himachal Pradesh, which links Farmer Producer Organisations (FPOs) to branded retail and e-commerce channels (Jamwal, 2026), can substantially improve price realisation for mountain produce.

The rapid expansion of high-density apple plantations in the Himalayan regions, especially in Jammu and Kashmir & Himachal Pradesh, demonstrates that when appropriate institutional support and market access are available, Himalayan farmers can have transition rapidly from subsistence to commercial agriculture (Mushtaq & Goswami, 2024). Digital platforms for quality grading, cold chain monitoring (IoT-based temperature sensors), blockchain-enabled traceability for premium GI-tagged products (Kashmiri saffron, Himachali apples, Uttarakhand organic grains), and mobile payment systems for direct farmer payments represent a suite of interconnected market-digital solutions with significant potential for Himalayan value chain upgrading.

5.2.3. Precision Horticulture and Crop Health Monitoring

The Himalayan zone's comparative advantage lies in high-value temperate horticulture, apples, pears, stone fruits, walnuts, saffron, medicinal and aromatic plants, products with premium domestic and export market potential. Digital technologies can significantly enhance the productivity and quality of these crops. IoT-integrated greenhouses in agriculture have demonstrated that sensor-based temperature monitoring and automated ventilation can prevent heat stress in lettuce and other leafy vegetables during summer months, improving produce quality and shelf life (Yun *et al.*, 2026; Fanourakis *et al.*, 2026). Drone-based multispectral imaging can enable early detection of fire blight, brown rot, and other fungal diseases in apple orchards that, when not detected early, can cause catastrophic crop losses. AI-powered image recognition applications that identify pest and disease symptoms from smartphone photographs have already been deployed in several Indian agri-tech platforms and hold considerable promise for mountain farmers with limited access to agricultural extension officers.

5.2.4. Women, Digital Agriculture, and the Feminisation of Mountain Agriculture

The feminisation of Himalayan agriculture, a direct consequence of male out-migration, creates both a challenge and a specific opportunity for digital agriculture interventions. Women farmers in mountain regions are performing an increasing proportion of agricultural labour, often without commensurate access to agricultural information, financial services, or technology. Digital platforms designed with gender sensitivity, voice-based advisory services in local languages (Pahari, Garhwali, Kashmiri), simplified interface design for low-literacy users, and women-led FPOs with digital market access, have the potential to simultaneously enhance agricultural productivity and women's economic agency.

The Krishi Sakhis initiative under the Digital Agriculture Mission, which trains women as certified para-extension workers for financial independence represents a significant institutional mechanism for channelling digital agriculture benefits through women (Government of India, 2024). Evidence from the Saagu Baagu programme in Telangana, where AI advisory services helped smallholding farmers, including women double their incomes (World Economic Forum, 2024), offers a proof of concept that is particularly relevant for mountain contexts.

5.3 Challenges to Digital Agriculture in the Himalayan Region

5.3.1. Infrastructural Deficits: Connectivity and Power

The most fundamental structural barrier to digital agriculture adoption in the Himalayan region is the deficit in digital and physical infrastructure. As of March 2024, rural tele-density in India stands at 59.19 per cent compared to 133.72 per cent in urban areas, a disparity that is more pronounced in remote mountain geographies where terrain and distance impose higher infrastructure costs (TRAI, 2024). Large parts of Himalayan India lack reliable broadband connectivity, with mobile data coverage being intermittent in high-altitude villages and interior valleys. Power availability is also irregular in many mountain communities, which complicates the operation of IoT sensors, charging of mobile devices, and functioning of digital extension platforms (Table 2).

BharatNet, the government's flagship rural broadband programme, has made progress in extending optical fibre connectivity to Gram Panchayats, but the 'last-mile' connectivity problem, connecting individual farm households at altitude, remains largely unresolved. Satellite internet technologies (such as VSAT and LEO satellite constellations) offer technical possibilities for remote mountain

connectivity but require substantial cost reductions and localised support infrastructure before they can serve as primary connectivity solutions for Himalayan farming communities.

5.3.2. Digital Literacy and Capacity Constraints

Digital literacy, the ability to effectively use digital tools and platforms, is a critical adoption prerequisite that is severely limited across much of rural Himalayan India. Lack of training programmes hinders the adoption of even basic digital tools like soil sensors and yield monitoring apps (Kumar et al., 2025). In mountain communities where formal education levels are higher than many other rural regions of India, yet where adult farmers, particularly women and elderly populations, have limited prior experience with smartphones and digital platforms, contextually appropriate digital literacy programmes are an essential investment.

Yuan & Sun (2024) identify digital literacy constraints as among the most critical barriers in their government–technology–smallholder framework analysis. The literature confirms that education level and prior exposure to ICTs are among the strongest predictors of digital agriculture adoption (Cui & Wang, 2023; Hoang & Tran, 2023). In the specific context of Himalayan out-migration, where the educated rural youth most likely to adopt and champion digital agriculture are disproportionately leaving their villages, communities face a paradox, the demographic most capable of mediating technology adoption is the demographic most likely to be absent. Extension services capable of filling this gap are themselves chronically understaffed in mountain regions.

5.3.3. Terrain, Fragmented Landholdings, and Scale Constraints

The physical geography of the Himalayan region imposes constraints on digital agriculture that have no direct parallel in the plains. Inaccessibility, precipitous terrain, and a fragile landscape are major drivers that hinder the application of modern innovation in the field of agriculture (Sati & Kumar, 2023). Standard precision agriculture technologies developed for flat, large-scale plains agriculture, GPS-guided tractors, variable rate application machinery, large-scale drone surveys, are not readily adaptable to steeply terraced, sub-hectare mountain farms where the topography itself constrains mechanisation (Table 2).

The high prevalence of extremely small and fragmented landholdings in India is especially acute in Himalayan contexts where terracing has produced highly fragmented land tenure patterns across multiple elevation bands. Scale constraints undermine the economic justification for capital-intensive digital agriculture investments at the individual farm level. Collective like FPO-mediated technology access, shared drone services, cooperative sensor networks, offer potential solutions but require institutional coordination capacities that are nascent in many mountain communities.

5.3.4. Socio-Cultural Resistance and Trust Deficits

Technology adoption in rural communities is not a purely rational-economic process but is mediated by social norms, community trust, and cultural attitudes toward innovation. Research in Himalayan regions document that farmers in traditional mountain communities often distrust externally introduced technologies that are not seen to respect local ecological knowledge and existing practices (KC *et al.*, 2022). The technology-as-external-imposition narrative creates adoption resistance that cannot be overcome by supply-side subsidies alone. Co-design approaches that integrate indigenous knowledge with digital tools, using AI to validate, rather than replace, traditional crop diversity management practices, are more likely to achieve sustained adoption.

Gender and generational dynamics further complicate adoption pathways. Women farmers, who now manage a disproportionate share of mountain agriculture, often have restricted independent

access to mobile phones, financial accounts, and training opportunities due to social norms, constraints that digital agriculture platforms must be designed to navigate rather than inadvertently reinforce. The elderly farmers who remain in Himalayan villages, while possessing invaluable ecological knowledge, may have limited aptitude and motivation for learning new digital skills absent sustained support systems.

5.3.5. Data Gaps and Context-Specificity of Digital Solutions

Standard digital agriculture algorithms and advisory systems are typically trained on data from intensive agricultural systems in the plains. Applying such systems to Himalayan conditions, with their distinctive soil types, elevation-dependent microclimates, indigenous crop varieties, and terrain-mediated pest dynamics, without local calibration risks generating agronomically inappropriate recommendations that erode farmer trust and undermine adoption (Table 2). India's Digital Agriculture Mission, for all its ambitions, focuses its pilot implementation on plains states (Uttar Pradesh, Gujarat, Maharashtra, Haryana, Punjab, and Tamil Nadu) (Government of India, 2024), with limited explicit attention to mountain-specific calibration requirements.

Table 2: Comparative Analysis of Digital Agriculture Opportunities and Challenges: Plains vs. Himalayan India

Dimension	Plains Agriculture	Himalayan Agriculture
Digital connectivity	Moderate–high; improving rapidly with 4G/5G rollout	Low–moderate; intermittent in high-altitude zones
Land holding size	Small but less fragmented; some medium holdings	Very small (<1 ha) and highly fragmented terraces
Mechanisation potential	High; flat terrain amenable to standard machinery	Very limited; precipitous terrain restricts mechanisation
Technology ecosystem	Established agri-tech sector; multiple startups active	Nascent; few mountain-specific solutions available
Climate risk profile	Drought, heat stress, flooding (plains-specific)	Extreme events, glacial melt, erratic precipitation, landslides
Labour availability	Relatively stable; mechanisation substitutes	Severe shortage; feminisation due to male out-migration
Market access	Better road infrastructure; eNAM accessible	Poor road connectivity; high transportation costs
Primary opportunity	Efficiency gains, input optimisation, yield improvement	Climate resilience, market access, high-value horticulture
Key barrier	Cost of technology, digital literacy, scale constraints	Connectivity, terrain, out-migration, context-specificity

5.4. Pathways Towards Inclusive Digital Agriculture in the Himalayan Region

5.4.1. Mountain-Specific Technology Design

The foundational requirement is the development of digital agricultural technologies specifically calibrated for mountain conditions. This includes lightweight, low-power IoT sensors that can operate on solar power in off-grid conditions; drone systems capable of navigating high-altitude winds and irregular terrain; offline-functional mobile applications that synchronise data when connectivity is available; and AI algorithms trained on Himalayan crop varieties, soil types, and microclimate datasets. The BharatNet programme needs to be complemented by satellite internet pilots in remote Himalayan blocks, while mobile extensions of the Krishi DSS must include mountain-specific layers for elevation, slope, aspect, and soil depth.

5.4.2. Community-Centred Adoption Models

Given the scale constraints and institutional characteristics of Himalayan farming, FPO-mediated collective adoption represents the most viable pathway for digital agriculture uptake. FPOs can pool resources to acquire shared precision technologies, drone services, sensor networks, mobile advisory platforms, and redistribute their benefits across member households. The Harvesting Farmer Network (HFN) Agritech model in Himachal Pradesh, linking FPOs to e-commerce and physical retail channels (Jamwal, 2026), demonstrates the potential of collective market access when anchored by a supporting agri-tech enterprise. Digital agricultural cooperatives, where FPOs collectively own and manage digital infrastructure, warrant specific policy support and financial facilitation through NABARD and the Small Farmers' Agribusiness Consortium (SFAC).

5.4.3. Digital Extension and Krishi Sakhi Networks

Strengthening digital extension networks, particularly through the Krishi Sakhi programme, represents a high-leverage intervention for Himalayan contexts. Krishi Sakhis, as locally embedded, trained, and certified para-extension workers, can serve as trusted intermediaries between digital agricultural platforms and mountain farming households that have limited direct platform access due to literacy, language, and connectivity constraints. Supplementing Krishi Sakhis with digital tools, tablet-based agricultural advisory applications, voice-based AI platforms in regional languages, GPS-linked crop scouting applications, can significantly multiply the reach and quality of agricultural extension in mountain geographies. Evidence from comparable para-extension models in East Africa (Outhwaite *et al.*, 2022) confirms that ICT-equipped community extension agents substantially outperform traditional extension in both reach and information quality.

5.4.4. Integration of Indigenous Knowledge with Digital Systems

A contextually appropriate digital agriculture strategy for the Himalayas must integrate, rather than displace, indigenous ecological knowledge. Traditional mountain crop diversity, water harvesting techniques, intercropping systems, and ecological pest management practices represent adaptive wisdom developed over centuries that digital tools can document, validate, and scale. AI-based knowledge management systems that record and make accessible traditional varietal knowledge, agroforestry practices, and community water management systems can serve both as cultural repositories and as practical resources for younger farmers and extension workers. Seed digital registries for indigenous Himalayan crop varieties represent an urgent digital heritage intervention with direct agricultural significance.

6. Policy Insights

Based on the comprehensions from the existing secondary literature, the following evidence-based policy insights are advanced:

- a) **Mountain-Inclusive Digital Agriculture:** The Digital Agriculture Mission must be explicitly extended to include pilot districts in Himalayan states (Jammu & Kashmir, Himachal Pradesh, Uttarakhand) within the first phase of implementation. Mountain-specific modules must be developed within the Krishi DSS for elevation-dependent climate analysis, terrace-scale soil profiling, and high-altitude crop mapping. The exclusion of Himalayan states from initial pilots must be urgently rectified.
- b) **Mountain-Specific Technology Fund:** A dedicated sub-fund within the Digital Agriculture Mission budget should be allocated for research and development of mountain-

appropriate digital agriculture technologies: low-power, off-grid IoT sensors; nano-drones for high-altitude field monitoring; offline-functional mobile advisory applications; and AI algorithms calibrated on Himalayan crop and climate datasets.

- c) **BharatNet Mountain Acceleration and Satellite Internet Pilots:** Achieving last-mile digital connectivity in Himalayan villages is a precondition for all other digital agriculture interventions. A time-bound Mountain Connectivity Mission, combining accelerated BharatNet Gram Panchayat connectivity, satellite internet pilots in high-altitude blocks, and community Wi-Fi hubs at Gram Panchayat offices, should be implemented with dedicated funding and a monitoring framework. The Rural Tele-density gap (currently 133.72% urban vs. 59.19% rural) must be tracked and targeted specifically for mountain sub-regions.
- d) **FPO-Mediated Collective Digital Agriculture:** NABARD, SFAC, and state agriculture departments should design FPO-specific digital agriculture support programmes that enable Farmer Producer Organisations in mountain regions to collectively acquire precision agriculture services, digital advisory subscriptions, and market-linkage platforms. Financial incentives digital adoption grants, and interest subsidies on technology loans for FPOs should be calibrated for mountain contexts where individual farm scale cannot justify standalone technology investment.
- e) **Krishi Sakhi Digital Empowerment Programme:** The Krishi Sakhi initiative should be scaled urgently in Himalayan states, with dedicated training modules in digital agricultural advisory, drone-based crop monitoring, mobile-based market platforms, and basic IoT device operation. Krishi Sakhis should be equipped with tablets pre-loaded with multilingual, offline-functional agricultural advisory applications tailored to Himalayan crops. Given the feminisation of Himalayan agriculture, investing in Krishi Sakhis as digitally empowered women extension agents is among the highest-return policy investments available.
- f) **Indigenous Knowledge-Digital Integration Programme:** ICAR and state agricultural universities in Himalayan states should be tasked with creating digital repositories of indigenous Himalayan crop varieties, traditional water management systems, agroforestry practices, and community ecological knowledge. This documentation should feed into the Krishi DSS as a locally validated decision supporter, ensuring that digital advisory services complement rather than replace mountain ecological intelligence.
- g) **Gender-Sensitive Platform Design Standards:** All digital agriculture platforms supported under the Digital Agriculture Mission should be required to meet gender-sensitive design standards: multilingual voice interfaces in regional mountain languages, simplified visual navigation for low-literacy users, and active outreach to women farmers and women-led SHGs. A Gender and Digital Agriculture Task Force should be constituted under the Ministry of Agriculture and Farmers Welfare to audit existing platforms for gender accessibility and mandate corrective design interventions.

7. Conclusion

This chapter has undertaken a systematic, research-augmented inquiry into the landscape of digital agriculture in India, with a sustained analytical focus on the Himalayan agro-ecological zone. The analysis generates several overarching conclusions. First, digital agriculture represents a genuine

transformative moment for Indian agriculture, backed by unprecedented policy ambition, dynamic agri-tech private sector, and an expanding body of evidence demonstrating farm-level productivity, resource efficiency, and income gains from precision technologies, IoT systems, AI advisory platforms, and digital market infrastructure. India's precision agriculture market is on a strong growth trajectory, and the Digital Agriculture Mission's DPI architecture, AgriStack, Krishi DSS, Digital Crop Survey, Soil Profile Mapping, provides the most comprehensive national digital agriculture infrastructure framework to date. Second, the Himalayan region presents a unique convergence of opportunity and challenge. The opportunity is real and multidimensional. Climate resilience through digital early warning & remote sensing systems; market access & value chain integration for high-value Himalayan products; precision horticulture for improved productivity & quality; and digital empowerment of women farmers navigating a feminised, labour-scarce agricultural environment are highly dependent on digital agriculture interventions. The challenges are equally real and deeply structural such as inadequate digital connectivity, severely fragmented smallholdings on precipitous terrain, pronounced out-migration of digitally capable rural youth, context-specificity gaps in existing digital solutions, and socio-cultural barriers to adoption. Third, the analysis reveals a systemic risk of 'digital exclusion by design', the risk that a national digital agriculture programme designed primarily around the plain's context will, through insufficient attention to mountain-specific needs, inadvertently deepen the development divide between agrarian plains and mountain communities. The pilots of the Digital Agriculture Mission are focused on six plains states; Himalayan states are not among the initial cohort. This is a significant omission that policy must urgently address. Fourth, the pathway to inclusive digital agriculture in the Himalayan region requires not merely technology transfer but institutional transformation, the development of FPO-mediated collective adoption models, mountain-specific technology design, digitally empowered Krishi Sakhi extension networks, integration of indigenous knowledge with digital systems, and gender-sensitive platform design. These institutional investments are preconditions for technology impact, not afterthoughts.

The Indian Himalayan Region stands at a crossroads. Without deliberate, contextually intelligent digital agriculture investment, it risks being left behind in India's agricultural transformation, its farming communities further marginalised by the dual pressures of climate change and technological exclusion. With such investment, grounded in co-design, community empowerment, and mountain ecological intelligence, digital agriculture holds the potential to revitalise Himalayan farming systems, retain rural populations, conserve agro-biodiversity, and build the climate resilience that the region urgently needs.
